Approximations in Time

▲□▶ ▲□▶ ▲ □▶ ▲ □▶ ▲ □ ● ● ● ●

- Basic theory
- Explicit Runge-Kutta methods
- Dual time-stepping
- Implicit vs explicit
- Summation-by-parts in time

Basic Theory

General linear PDE:

$$u_t = P(\partial/\partial x)u \tag{1}$$

Discretize in space and time separately (method of lines):

$$U_t = QU \tag{2}$$

(*Q* is obtained by discretizing the PDE in space, including boundary conditions. Coupled space-time discretizations are also possible - e.g. Lax-Wendroff scheme, not the focus here).

Stability: Assume that *Q* can be diagonalized as $T^{-1}QT = \Lambda$.

Test equation:

$$u_t = \lambda u. \tag{3}$$

If a time stepping scheme applied to (3) is stable for all eigenvalues λ of Q, then it is stable also for (2).

Basic Theory

Ex:
$$\frac{u^{n+1}-u^n}{\Delta t} = \lambda u^n$$
 (explicit), $\frac{u^{n+1}-u^n}{\Delta t} = \lambda u^{n+1}$ (implicit).

Explicit methods in general stable if

i) $\text{Real}(\lambda) \leq 0$ (Petrowski) and

ii) $|\Delta t \lambda|$ sufficiently small (Von Neumann).

Centered approx. for first order PDE \Rightarrow Imag(λ) ~ $\frac{1}{\Delta x}$ Centered approx. for second order PDE \Rightarrow Real(λ) ~ $\frac{1}{\Delta x^2}$

Implicit methods are often stable for <u>all</u> Δt (A-stability).

A and L stability

Def: A-stability: $|u^{n+1}| < |u^n|$ for all Real $(\lambda) \le 0$, all $\Delta t > 0$.

Sometimes A-stability is not good enough, no damping of non-physical oscillations.

Def: L-stability: An A-stable method is also called L-stable if

$$\frac{|u^{n+1}|}{|u^n|} \to 0 \quad \text{as} \quad |\Delta t\lambda| \to \infty$$

▲□▶ ▲□▶ ▲ □▶ ▲ □▶ ▲ □ ● ● ● ●

A and L stability

Ex: The θ -method

$$\frac{u^{n+1} - u^n}{\Delta t} = \lambda(\theta u^{n+1} + (1 - \theta)u^n).$$
$$u^{n+1} = \underbrace{\frac{1 + \Delta t \lambda(1 - \theta)}{1 - \Delta t \lambda \theta}}_{Z} u^n$$

 $|Z(\Delta t\lambda)| \le 1$ for all Real $(\Delta t\lambda) \le 0 \implies A$ -stable, all θ

Let $\Delta t \lambda \to \infty \Rightarrow |Z| = |\frac{1-\theta}{\theta}|$

 θ = 1, Backward Euler, $O(\Delta t)$, <u>L-stable</u> θ = 1/2, Trapezoidal, $O(\Delta t^2)$, not L-stable

- nac

Runge-Kutta methods

$$\frac{du}{dt} = F(t, u)$$

- R-K are one-step methods, no start-up problems.
- *s* intermediate "stages" computed at each time step.
- *F*(*t*, *u*) evaluated in each stage.

Explicit R-K (ERK):

$$k_{1} = F(t_{n}, u^{n})$$

$$k_{2} = F(t_{n} + c_{2}\Delta t, u_{n} + \Delta t a_{21}k_{1})$$

$$k_{3} = F(t_{n} + c_{3}\Delta t, u_{n} + \Delta t (a_{31}k_{1} + a_{32}k_{2}))$$
...
$$k_{s} = F(t_{n} + c_{s}\Delta t + \Delta t (a_{s1}k_{1} + ... + a_{s,s-1}k_{s-1}))$$

$$u^{n+1} = u^{n} + \Delta t (b_{1}k_{1} + ... + b_{s}k_{s})$$

Runge-Kutta methods

A one-step method applied to test eq. leads to $u^{n+1} = Z(\lambda \Delta t)u^n$. (*Z* polynomial (explicit) or rational (implicit) appr. of $e^{\lambda \Delta t}$)

Stability region: All μ in the complex plane such that $|Z(\mu)| \leq 1$. Ex: $u^{n+1} = Z(\mu)u^n = (1 + \mu) + \frac{\mu^2}{2!} + \frac{\mu^3}{3!} + \frac{\mu^4}{4!}u^n$ Forward Euler Huen's method Classical RK4 KH9. KIL1-

Dual time-stepping

Assume we want to solve a transient system using an <u>implicit</u> scheme.

$$U_t + Q(U) = F. \tag{4}$$

E.g. Euler backward \Rightarrow

$$\frac{U^{n+1} - U^n}{\Delta t} + Q(U^{n+1}) = F^{n+1}$$
(5)

How do we solve (5) for U^{n+1} without solving a complicated nonlinear equation? Trick: Let $U^* = U^{n+1}$, add $\frac{\partial U^*}{\partial \tau}$ to (4) \Rightarrow

$$\frac{\partial U^*}{\partial \tau} + \underbrace{\frac{U^*}{\Delta t} + Q(U^*)}_{\tilde{Q}(U^*)} = \underbrace{F^{n+1} + \frac{U^n}{\Delta t}}_{\tilde{F}}$$
(6)

Can be integrated using a <u>fast steady-state solver</u>.

Explicit vs. Implicit Methods

- Explicit Methods
 - + Simplicity
 - + Easy to program
 - + No system to solve
 - Small time-steps for stiff problems
- Implicit Methods
 - + Large time-steps allowed
 - + Fast for steady-state
 - Complicated
- Research fields
 - – IMEX
 - – Implicit for large nonlinear equations

- Methods for bounded error growth
- – SBP-SAT in time

SBP-SAT in time: the first derivative

Consider the scalar constant coefficient problem:

$$u_t + \lambda u = 0, \quad 0 \le t \le T, \tag{7}$$

where λ is a real constant. The energy estimate with u(0) = f is

$$u(T)^{2} + 2\lambda ||u||_{L_{2}}^{2} = f^{2},$$
(8)

where the L_2 norm is defined as $||u||_{L_2}^2 = \int_0^T u^2 dt$.

The fully discrete approximation of (7) becomes

$$\vec{u}_t + \lambda \vec{u} = P^{-1} \tau (u_0 - f) \vec{e}_0, \tag{9}$$

where

$$\vec{u}_t = D_1 \vec{u} = P^{-1} Q \vec{u}.$$
 (10)

SBP-SAT in time: the first derivative

By choosing $\tau = -1$ and applying the discrete energy method to (9) we find

$$u_N^2 + 2\lambda \|\vec{u}\|_P^2 = f^2 - (u_0 - f)^2, \tag{11}$$

- ロト・日本・日本・日本・日本

where $\|\vec{u}\|_{P}^{2} = \vec{u}^{T} P \vec{u}$. The estimate (11) mimics the continuous target (8), only introducing a small additional damping term.

The SBP-SAT first derivative formulation is unconditionally stable (arbitrary Δt) and high order accurate.

The time interval can be divided into an arbitrary number of subdomains, allowing for a multi-stage formulation of the method with reduced number of unknowns.

The multi-stage formulation superconverges at each final multi-stage time. For an SBP-SAT approximation of order (p,2p) with diagonal norm, the full 2p order is obtained.

SBP-SAT in time: the second derivative

We extend the scalar constant coefficient case to the second order equation:

$$u_{tt} + \alpha^2 u_t + \beta^2 u = 0, \quad 0 \le t \le T$$
 (12)

where α^2 and β^2 are positive real constants. Given two initial conditions u(0) = f and $u_t(0) = g$

$$u_t(T)^2 + \beta^2 u(T)^2 + 2\alpha^2 ||u_t||_{L_2}^2 = g^2 + \beta^2 f^2,$$
(13)

is found, which is the target for our discrete energy estimate.

We can impose $u_t(0) = g$ in the usual manner. However, implementing u(0) = f is more complicated and needs careful treatment.

SBP-SAT in time: the second derivative

We transform (12) into a system of first order differential equations. Setting $u_t = v$ and applying the SBP-SAT technique for the first derivatives yield

$$D_1 \vec{u} - \vec{v} = P^{-1} \tau_0 (u_0 - f) \vec{e}_0$$

$$D_1 \vec{v} + \alpha^2 \vec{v} + \beta^2 \vec{u} = P^{-1} \tau_{0t} (v_0 - g) \vec{e}_0.$$
(14)

The first equation in (14) above can be used to define a modified discrete first derivative, with the weak SAT condition added to it. Indeed, we let $\tilde{\vec{u}}_t = \vec{v}$, which gives

$$\tilde{\vec{u}}_t = \vec{u}_t - P^{-1}\tau_0(u_0 - f)\vec{e}_0, \tag{15}$$

where $\vec{u}_t = D_1 \vec{u}$ as in (10). Note also that the modified discrete first derivative $\tilde{\vec{u}}_t$ has the same order of accuracy as \vec{u}_t .

SBP-SAT in time: the second derivative Inserting (15) into the second equation in (14), leads to

$$\tilde{\vec{u}}_{tt} + \alpha^2 \tilde{\vec{u}}_t + \beta^2 \vec{u} = P^{-1} \tau_{0t} ((\tilde{u}_0)_t - g) \vec{e}_0,$$
(16)

where the modified discrete second derivative is defined by applying the first derivative operator again on $\tilde{\vec{u}}_t$:

$$\tilde{\vec{u}}_{tt} = D_1 \tilde{\vec{u}}_t. \tag{17}$$

With the choice $\tau_0 = \tau_{0t} = -1$, the discrete energy method gives

$$((\tilde{u}_N)_t)^2 + \beta^2 u_N^2 + 2\alpha^2 \|\tilde{\vec{u}}_t\|_P^2 = h^2 + \beta^2 f^2 - ((\tilde{u}_0)_t - g)^2 - \beta^2 (u_0 - f)^2,$$
(18)

which is very similar to the continuous estimate (13).

In a boundary value problem with u = f, u = g posed at different boundaries, the standard SBP-SAT technique could have been used.

Summary of SBP-SAT in time

- First derivative
 - + High order accurate
 - + Unconditionally stable
 - + Superconverging at last time step
 - + Fully discrete energy estimates
 - + Preserves nonlinear stability
 - – Large system to solve
- Second derivative
 - + High order accurate
 - + Unconditionally stable
 - + Fully discrete energy estimates
 - – Large system to solve
 - - Wide operators for initial value problems

Exercises/Seminars

- Discretise the advection-diffusion equation, and prove stability, first semi-discrete, next fully discrete, using SBP in time.
- Discretise the initial value problem for the wave equation, and prove stability, first semi-discrete, next fully discrete, using SBP in time.
- Discretise the boundary value problem for the wave equation, and prove stability, first semi-discrete, next fully discrete, using SBP in time.

• Prove that SBP in time preserves semi-discrete stablity.
